

NxM Templates for SuperCDMS SNOLAB Run 4 — Ge Activation Data

K-line event selection · free-pretrigger two-exponential fits (*future step: three-, four-exponential fits*) · 1x1
and NxM (PCA) templates

Table of Contents

1. **Dataset:** Ge activation K-line event selection, raw trace cache (13 detectors)
2. **Pulse fit:** 100 kHz low-pass, free-pretrigger two-exponential fit, alignment at 16050
3. **Data cleaning:** fit_ok, NRMSE valley cut (0.4), rise-time ceiling (0.3 ms)
4. **Cross-checks:** cuts remove noise, real pulses stay; slow-fall follow-up
5. **Template generation:** 1x1 weighted template, NxM PCA templates
6. **Deliverables and future steps:** cdmsbats ROOT files; three-, four-exponential fits
7. **Backup:** weak detectors, rise-time cut details, full results for every zip

Ge activation dataset - R4

Credit: Prof. Tarek Saab

- Per detector, Prof. Saab's study marked the 10.37 keV K-line position in **PTOFamps** (the red line in each panel below)
- A **PTOFamps** window bracketing the red line: position $\times/\div 1.35$, a rough eyeballed choice; deliberately minimal, no other cuts
- For every selected event: cache the fully unprocessed raw MIDAS traces of all channels + event metadata, saved as per-series pickle files (reusable for any later analysis)
- Events in the window per zip: Z1 10.1k Z4 26.1k Z6 17.0k Z7 2.2k Z9 2.6k Z10 7.6k Z13 9.1k Z15 4.2k Z16 1.6k Z18 22.1k Z19 23.3k Z22 25.0k Z24 22.9k (total 174k)
- **This talk focuses on Z7, the best detector; all other detectors are covered in the backup slides**

All 13 detectors, PTOFamps spectra (Prof. Saab's study)

Fit quality at a glance: event × channel grids

- Real events and noise triggers can be told apart by visual comparison (no cut applied at this stage)

NOISE

REAL PULSE

Per-trace algorithm: low-pass → fit → align

1. **Low-pass** — 100 kHz Butterworth
2. **Normalize** — subtract the baseline (median of the pre-pulse samples), scale the trace to unit peak
3. **Fit** — two-exponential model:

$$y(t) = A[e^{-(t - t_0)/\tau_{\text{fall}}} - e^{-(t - t_0)/\tau_{\text{rise}}}] + b$$

t_0 = pretrigger, free within 16050 ± 3000 samples (τ_{rise} , τ_{fall} : rise / fall time)

Fit parameters: A amplitude · τ_{rise} rise time constant · τ_{fall} fall time constant · t_0 pulse onset (pretrigger) · b baseline

4. **Two quality checks per trace** (calculated and recorded here, not cut yet):

- **fit_ok** — amplitude is positive, and the pulse rises faster than it falls
- **NRMSE** — RMS of the fit residual ÷ pulse peak (smaller = better fit)

5. Align — shift each trace to a common pretrigger

- Shift the measured trace by (fitted pretrigger – 16050) — a pure translation. Drawn at the common pretrigger, the fitted curves stack into one shape family:

All fit_ok fitted curves (Z7 PBS1) — no cut

After $\text{NRMSE} \leq 0.4$ (Z7 PBS1) — one tight shape family

Quality cut 1: $\text{NRMSE} \leq 0.4$ — where the number comes from

- NRMSE of fit_ok events is bimodal: good fits (median ≈ 0.05 – 0.1) vs noise triggers (≈ 1 – 2), valley at ≈ 0.4 – 0.5
- The cut sits in the valley — it is read off the distribution, not tuned on the templates
- Weak detectors (Z1, Z4, Z6, Z18, Z19, Z22, Z24): same bimodal picture, noise peak dominates

The rejected population is noise — verified in the raw traces

- Event grids of NRMSE-rejected events (median NRMSE > 0.4 across channels): the raw traces show no pulse — the cut removes noise triggers, not physics

Z7: NRMSE-rejected events — raw traces are noise

Z7 PBS1 — passes the cut (kept) — cut away = rejected
faint blue = measured traces 1931 kept / 77 cut (~3.8%)

Follow-up 1 — the slow-fall tail is a one-channel artifact

- The post-cut fan still shows slow-fall tails → sample them: $\text{NRMSE} \leq 0.4$ AND $\tau_{\text{fall}} > 1.5$ ms, 10 random events, raw vs fit drawn in all 12 channels
- The sampled events are real pulses → kept. Their extreme fall times trace to one channel: only PDS2 swings (τ_{fall} median 0.51 ms vs ≈ 0.25 ms elsewhere) — a low-frequency disturbance
- Conclusion: no τ_{fall} cut — slow-fall events passing NRMSE stay in; the extreme tail is a one-channel artifact, not a slow pulse
- PDS2 alone: can not make useful templates; hard to fix in analysis/software, the noise itself needs to be fixed
- Temporary solution: use the PDS1 template in place of PDS2 (applied in the delivered ROOT files)

Z7, 3 sampled slow-fall events: normal in PBS2/PCS2/PES2, swings only in PDS2

Fitted τ_{fall} distribution, same 0–7 ms axis:

Z7 PAS1 — normal channel: narrow
(median 0.25 ms)

Z7 PDS2 — bad channel: broad tail
(median 0.51 ms)

Template family 1 — analytic 2-exp, NRMSE-weighted (1x1)

- NRMSE-weighted mean of the fit_ok 2-exp curves
- Smooth & noise-free by construction
- ROOT histograms, peak-normalized (+ summed PT / PS1 / PS2)

Z7 PBS1 — blue: the fitted curves (200 of 1931 drawn); red: the 1x1 template

Same curves, two averages (zoomed): NRMSE-weighted (the 1x1 template) vs plain mean (= nxm0); dashed gray = the other one

Template family 2 — NxM PCA templates

- Per-channel PCA over the fitted curves ($\text{fit_ok} + \text{NRMSE} \leq 0.4$)
- nxm0 = mean shape; nxm1 – 4 = principal components; $\text{real pulse} = \sum_i \text{amp}_i \cdot \text{nxm}_i$
- $\text{PC1} + \text{PC2} \approx 96\text{--}98\%$ of the shape variance; delivered peak-normalized

Z7 PBS1: nxm0 (mean) + nxm1 – 4 (PCs) — the oscillating components encode rise/fall-time variation

Template file

- Two template sets for all 13 detectors: 1x1 (2-exp weighted) + NxM PCA
- In cdmsbats_config feature branch, ready for merge

Future Steps

- Three-, four-exponential fits
- Exercise NxM processing
- Other detectors: worse noise, a few more cuts added, in the backup slides

Backup — weak detectors (example: Z22)

- Z1 / Z4 / Z6 / Z18 / Z19 / Z22 / Z24: K-line sits inside the noise population — the PTOF window admits a noise-dominated mixture
- Same bimodal NRMSE picture, noise peak dominates; the same 0.4 cut digs the real pulses out — Z22 PCS1: 7198 kept / 4788 cut (~40%)
- Kept bundle broader than on quiet detectors; steep red curves = fits latching onto sharp noise spikes, not fast pulses being cut
- $\tau_{\text{rise}} \leq 0.3$ ms (after NRMSE): removes 55–74% on weak zips (Z22: 71%) vs 1.6% on Z7 — residual slow drift

Z22 PAS1: NRMSE histogram — noise dominates

Z22 PCS1: kept (green) vs cut (red)

Z22 PCS1 after $\text{NRMSE} \leq 0.4 + \tau_{\text{rise}} \leq 0.3$ ms — final shape family (760 fits)

Backup — the $\tau_{\text{rise}} \leq 0.3$ ms ceiling (PCA input)

- Slow baseline drift survives NRMSE (a slow 2-exp hugs it) → mimics a slow rise
- Fast pulses at $\tau_{\text{rise}} \approx 0.1$ ms (p90 ≈ 0.15 ms) → ceiling at 0.3 ms blocks the drift tail
- Removed after the NRMSE cut: Z7 1.6% (quiet 2–6%) — weak 55–74% (Z22 71%) — all zips 54%
- Trade-off: trims the very slowest genuine pulses → decision pending

Z7 PAS1: fitted τ_{rise} (median 0.105 ms) and τ_{fall} distributions

Backup — τ_{rise} cut: a good vs a bad channel (Z7)

- Good channel PBS1: tight clean bundle — the $\tau_{\text{rise}} \leq 0.3$ ms cut removes $\sim 0\%$ (nearly free on quiet channels)
- Bad channel PDS2: broad, messy fan — the channel itself is bad; the cut trims the slow-rise curves, 1462 $\rightarrow$ 1154 (21%)

PBS1 (good) — $\text{NRMSE} \leq 0.4$

PBS1 (good) — $+\tau_{\text{rise}} \leq 0.3$ ms (unchanged)

PDS2 (bad) — $\text{NRMSE} \leq 0.4$

PDS2 (bad) — $+\tau_{\text{rise}} \leq 0.3$ ms (slow risers trimmed)

Backup — what the τ_{rise} cut removes: noise NRMSE missed (Z22)

- Exactly the events that PASS $\text{NRMSE} \leq 0.4$ but are REMOVED by $\tau_{\text{rise}} \leq 0.3$ ms — the noise 0.4 let through, 0.3 catches
- PCS1 / PDS1 pass at $\text{NRMSE} \approx 0.15$ (a slow 2-exp hugs a slow baseline drift) — but the raw trace has no clean fast pulse
- Trade-off: the same cut also trims genuine slow-rise pulses — documented, decision pending

Z22: 3 events $\times$ PAS1/PBS1/PCS1/PDS1 — pass $\text{NRMSE} \leq 0.4$, removed by $\tau_{\text{rise}} \leq 0.3$ ms; PCS1/PDS1 are pure slow drift

shift-aligned measured traces · figure: zip7_lp_aligned_overlay.png

Blue = measured LP traces shifted by (fitted pretrigger - 16050); red = point-by-point mean of ALL fit_ok events; orange = NRMSE-weighted mean of the fitted curves ($w = 1/\max(\text{NRMSE}, 0.01)^2$). Rise edges line up at 16050.
